this monograph is motivated by the challenges faced in designing reliable vlsi systems in modern vlsi processes the reliable operation of integrated circuits ics has become increasingly difficult to achieve in the deep submicron dsm era with continuously decreasing device feature sizes combined with lower supply voltages and higher operating frequencies the noise immunity of vlsi circuits is decreasing alarmingly thus vlsi circuits are becoming more vulnerable to noise effects such as crosstalk power supply variations and radiation induced soft errors among these noise sources soft errors or error caused by radiation particle strikes have become an increasingly troublesome issue for memory arrays as well as combinational logic circuits also in the dsm era process variations are increasing at a significant rate making it more difficult to design reliable vlsi circuits hence it is important to efficiently design robust vlsi circuits that are resilient to radiation particle strikes and process variations the work presented in this research monograph presents several analysis and design techniques with the goal of realizing vlsi circuits which are radiation and process variation tolerant

deep sub micron dsm processes present many changes to very large scale integration vlsi circuit designers one of the greatest challenges is crosstalk which becomes significant with shrinking feature sizes of vlsi fabrication processes the presence of crosstalk greatly limits the speed and increases the power consumption of the ic design this book focuses on crosstalk avoidance with bus encoding one of the techniques that selectively mitigates the impact of crosstalk and improves the speed and power consumption of the bus interconnect this technique encodes data before transmission over the bus to avoid certain undesirable crosstalk conditions and thereby improve the bus speed and or energy consumption
