Muscle Metabolism During Exercise

1971

Howard G. Knuttgen of biology Boston University 2 Cumington Department Street Boston 02215 Massachusetts USA. The relationship of the formation of lactate acid to skeletal muscle energy release in exercising humans was first explored by A. V. Hill and co-workers. The term oxygen debt was suggested by them to describe the excess oxygen consumption of recovery which they felt was closely related to a combination of their work and the earlier work of Krogh and Lindhard. It resulted at that time in the belief that a certain amount of energy release during the transition from rest to exercise was provided by a non-aerobic source, glycolysis. The resulting accumulation of lactic acid as lactate in the body required an extra consumption during recovery for its oxidative removal. Jervell subsequently showed that in exercise the greatest accumulation in blood took place during the first few minutes. He felt that the blood lactate increase was due to a shortage of oxygen during the transition period. The observation was also made for the first time that the increased level of lactate due to exercise could be made to fall faster if mild exercise was employed by the subjects in place of sedentary recovery. The work of Margaria, Edwards, and Dill appeared in 1933. They observed that exercise treadmill running could be carried on at low levels without significant changes in resting levels of blood lactate.
